

Retail Intelligence: From Data to Decisions

Executive Decision Report & Capstone Presentation

Retail Business Intelligence Dashboard | RABTECH Academy | Task 06

Purpose: Translate dashboard analysis into an executive-ready decision framework.

2. Executive Summary

- The dashboard converts retail data into an executive view of revenue, customer, product and regional performance.
- Interactive KPIs and filters help decision-makers move from high-level monitoring to focused analysis.
- The recommended operating model is: Monitor → Diagnose → Act → Measure.
- This report focuses on practical decisions, measurable actions and a repeatable review cycle.

3. Business Problem

- Retail teams often have data but lack a single decision-ready view.
- Important questions can be difficult to answer quickly: What is changing? Where is the change? Which products or customers need attention?
- The dashboard addresses this gap by combining KPIs, trends, geography and categorical filters in one analytical view.
- Business objective: improve visibility, prioritization and speed of decision-making.

4. Data & Methodology

- Data is organized into business dimensions such as time, customer, product and geography, with measurable sales outcomes.
- Workflow: Data preparation → KPI definition → Interactive visualization → Drill-down analysis → Business interpretation.
- Quality checks should include missing values, duplicates, inconsistent categories and date/number formats.
- Insights should be validated against the underlying dashboard filters before operational use.

5. KPI Framework

- Revenue — tracks overall sales value and business growth.
- Average Order Value (AOV) — indicates the average value generated per order.
- Customer Acquisition Cost (CAC) — measures the cost of acquiring customers.
- Churn Rate — indicates customer loss over a defined period.
- Use the same KPI definitions consistently across monthly executive reviews.

KPI	Executive use
Revenue	Business scale and sales movement
AOV	Order-value efficiency
CAC	Acquisition efficiency
Churn Rate	Customer retention signal

6. Revenue & Profit Performance

- Use the dashboard trend view to identify growth periods, slowdowns and unusual movements.
- Compare performance across time periods before deciding whether a change is structural or temporary.
- Use category and product drill-downs to identify the contributors behind aggregate movement.
- Management action: investigate material deviations, document the driver, and assign an owner for follow-up.

7. Customer & Product Insights

- Customer analysis should separate acquisition, retention and order-value behavior.
- Product analysis should highlight high-contribution categories and products requiring attention.
- Use slicers to compare customer segments, product groups and time periods without losing the executive context.
- Action principle: prioritize segments/products where business impact and intervention feasibility are both high.

8. Regional & Trend Analysis

- Geographic views help identify concentration, under-served areas and regional variation.
- Temporal drill-down supports year → quarter → month analysis where the dataset permits.
- Categorical drill-down supports category → sub-category/product analysis where available.
- Avoid treating descriptive regional differences as causal without additional evidence.

9. Key Risk Areas

- Data-definition risk: KPI calculations can become inconsistent if business definitions are not documented.
- Data-quality risk: missing, duplicate or inconsistent records can distort trends.
- Concentration risk: dependence on a small set of products, customers or regions can increase exposure.
- Execution risk: insights create value only when owners, actions and review dates are assigned.

10. Three Strategic Recommendations

- 1. Build a weekly KPI control loop: review Revenue, AOV, CAC and Churn together, then investigate material changes.
- 2. Create targeted product/customer action lists: use dashboard filters to identify priority segments and assign owners.
- 3. Introduce an exception-based management process: escalate unusual trends or regional/category deviations instead of manually reviewing every record.

11. ROI & Implementation Roadmap

- Scenario-based ROI model (illustrative): quantify benefit from incremental revenue + avoided cost, then subtract implementation/operating cost.
- Recommended measurement: baseline → 30-day pilot → 60-day optimization → 90-day review.
- Track revenue impact, AOV movement, acquisition efficiency, churn movement and operating effort.
- Important: ROI values should be replaced with organization-approved financial assumptions before business use.

Illustrative ROI framework

$$\text{ROI \%} = (\text{Incremental benefit} - \text{implementation/operating cost}) \div \text{implementation/operating cost} \times 100.$$

Use approved business assumptions and actual baseline values before presenting a financial ROI claim.

12. Conclusion & Business Impact

- The dashboard creates a single decision layer for retail performance monitoring.
- Its strongest value is not only visualization, but the connection between KPI movement and a repeatable management action.
- Next step: connect each priority insight to an owner, target, action and review date.
- Outcome: a practical analytics workflow that supports faster, evidence-based retail decisions.
